# **LAKE ANDES SEDIMENT SURVEY**

## **INTRODUCTION**

The purpose of this report is to present sediment survey information on the south unit of Lake Andes. This information was acquired between the dates of February 1 and 25, 1993. This survey was initiated as part of the Lake Assessment Project in order to assess the current distribution of the sediment, water depth variation, and lake volumetric calculations for sediment and water. This report addresses procedures used to obtain the data, a listing of the data, the analysis of the data, and the potential restoration alternatives for Lake Andes.

## **BACKGROUND INFORMATION**

Lake Andes is a natural lake which has had a history of going dry on average every 11-14 years. At the present, the lake is in a state of stagnation and will continue in this state, or eventually become dry, unless a considerable amount of rainfall and snowmelt occurs in the next few years. The water supply for the lake comes almost entirely from watershed runoff. Lake Andes has a fairly small watershed relative to its lake size thereby resulting in a shortage of water during drought conditions. In 1934, a high water elevation of 1437.25 feet msl was established for Lake Andes via the construction of an artificial outlet. This structure permanently lowered the high water elevation of 1450 feet msl required to overflow the natural outlet by 12.75 feet. Other structures have been constructed on both the watershed and the lake to allow for effective management of the water. However, these structures do not deter the high evaporation rates of this semiarid region (i.e. - average annual evaporation and transpiration rates are 41.2 inches per year, average annual precipitation rate is 22.4 inches per year).

## **SEDIMENTATION SURVEY**

The survey was conducted between the dates of February 1 and 25, 1993. The survey crews consisted of two crews of three people each to acquire data at each station along with a two person crew at the base station to survey each station and record the data. The data was collected through the ice by drilling holes at surveyed stations (via-TOPCON GTS-3B) and recording the water and sediment depth. A baseline with cross-sections (600 foot increments) was initially established (figure 1). Holes were then drilled at 300 foot increments along each cross-section to establish a grid with 368 cells (cell size 600 ft. x 300 ft.). At each station, water depth (via. stadia rod) and sediment depth (via. ½" rebar)(figures 2a-2j) were recorded. On each cross-section, shore points and high water marks were also recorded in order to determine the current lake capacity and high water aerial extent.

## DATA ANALYSIS

The sediment and water data was initially plotted by hand on engineering grid paper and contoured. The perimeter of the lake (shore points, high water marks) was then digitized in order to determine the area of the lake. The data was then loaded into a spreadsheet program (QUATTRO PRO) and analyzed to determine the following selected statistical parameters:

### LAKE ANDES CHARACTERISTICS (SOUTH FORK)

MEAN WATER DEPTH	=	3.10	FEET
MEAN SEDIMENT DEPTH	=	4.68	FEET
MEDIUM WATER DEPTH	=	3.30	FEET
MEDIUM SEDIMENT DEPTH	=	4.80	FEET
LAKE AREA (SHORE POINT)	=	1598	ACRES
LAKE AREA (HIGH WATER)	=	1710	ACRES
VOLUME OF WATER (SP)	=	4954	ACRE-FEET
VOLUME OF SEDIMENT	=	7479	ACRE-FEET
MAXIMUM WATER DEPTH	=	10.6	FEET
WATER DEPTH STD. DEV.	=	.62	FEET
SEDIMENT DEPTH STD. DEV.	=	1.15	FEET

40% water  
60% muck!

A graphical depiction of sediment and water depth frequency is displayed in figures 3 thru 6. An analysis was made to determine if there was a correlation between water depth and sediment accumulation (figure 7). It was established by this plot that there is not a correlation between sediment accumulation and water depth.

## RESTORATION ALTERNATIVES

There are several alternatives available for the restoration of Lake Andes. These alternatives listed below were chosen on the basis of effectiveness, cost, and their probability of success :

1. No action
2. Selective dredging
3. Land based removal of sediment
4. Dilution/Flushing

### No Action

If no action is taken to restore the quality of Lake Andes and its watershed, problems will continue and may become more serious. Sediment buildup will continue and the depth will decrease until the lake is a wetland or marsh which could only be used by waterfowl.

deposition rate =

### Selective Dredging

If sediment input from the watershed is found to be minimal or minimized by the implementation of BMP's in the watershed, dredging selected areas on the south unit of the lake may be a good option. It has been demonstrated that sediment removal also helps to retard nutrient releases. Certain areas where dredging takes place may provide significant habitat for fish and other living organisms which may prevent or minimize fishkill events. Selective dredging is less expensive and less time consuming than whole lake dredging. The total amount of sediment and the location of the greatest sediment concentrations would still need to be calculated. The average operational cost of an eight inch dredge for a year is \$200,000 , not including startup costs of approximately \$75,000.

### Land Based Removal of Sediment

This method may be the most feasible since Lake Andes has a high tendency to go dry approximately once every twenty years. It may be in the best interest of this project to use land-based equipment to remove the sediment if this event takes place in the next few years. The end result of the land based removal would be similar to that of selective dredging. The advantage of land based removal is that it can be accomplished with conventional equipment such as draglines, bulldozers, or scrapers.

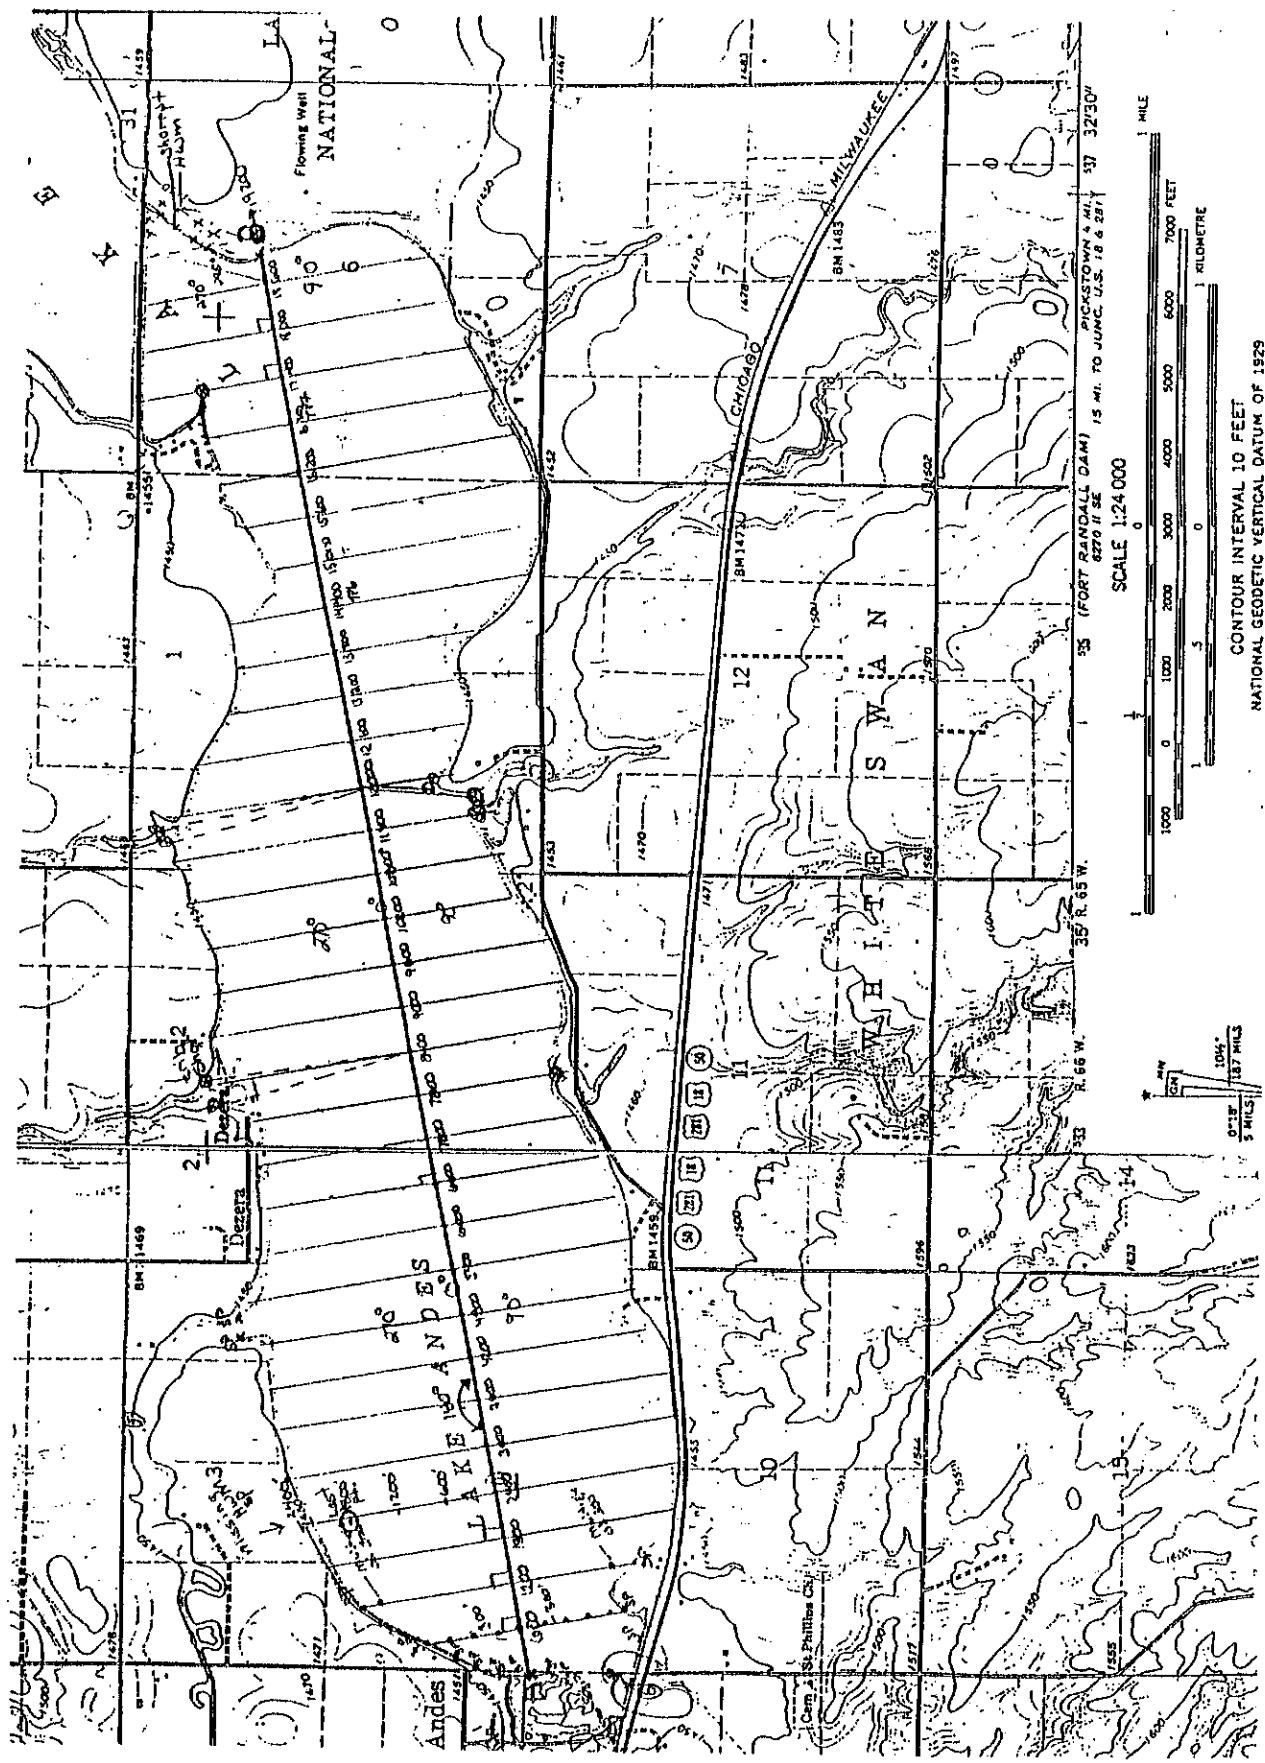

### Dilution/Flushing

In the event that the Lake Andes-Wagner/Marty II irrigation project is completed within the Lake Andes area a dilution/flushing restoration alternative may be created with off-peak pumping into the south unit. If the depth of the south unit is maintained at the high water elevation of 1437.25 feet msl it still may be necessary to dredge selectively to increase the depth in certain areas of the lake.

## **CONCLUSIONS**

Lake Andes has the characteristics of a typical South Dakota lake. It is concave and shallow and has a tendency to fill with sediment. Because of the negative water balance (precipitation - (evaporation + transpiration)) and low watershed/lake area ratio, this lake will have a tendency to have a highly fluctuating water level. Currently, the mean water depth is 3.10 feet and the mean sediment depth is 4.68 feet. If the recreational uses, wildlife and water quality are to be maintained and improved, an effort should be made to increase the lake water depth and volume through the implementation of a dredging program and water conservation measures.
